BS EN 12326-1:2004 Testing Explained

BS EN 12326-1:2004 is the new European standard for slate and stone products for discontinues roofing or cladding. This replaces the old BS 680-2:1971.

Following is a brief explanation, explaining the tests and standards our slate reaches in order to conform to the new standard.

1. Dimensions

Tolerances are provided for the length, width, individual thickness, flatness, rectangularity and edge deviation, of the slate being tested.

The packed thickness for 100 slates must be calculated for every pallet to allow for the calculation of the average roofing slate thickness, with a reduction applied on the surface finish.

2. Flexural Strength

The slate test samples are supported on two bars and a third central bar is pushed down on the slate until failure occurs. The test is carried out both parallel and perpendicular to the long edge of the roofing slate. From the results gained a characteristic modulus of rupture is calculated (basically a ratio) and the larger of the two values is used for calculating the minimum individual thickness of the roofing slate.

4. Water Absorption

The slate is dried to a constant weight; it is then immersed in water. The absorption percentage is determined via the difference in mass. If the value obtained is less than 0.6%, the slate is classed as A1, whereas, if it is above 0.6% it is classed A2.

5. Freeze-Thaw Test

This test is only required on A2 classed slates. The slate is submitted to 100 cycles of freezing in air, followed by thawing in water, once this is complete the flexural strength test is repeated. If there is a significant change in results, the slate is deemed not suitable and does not pass the European standard.

Non-Carbonate Content

This test verifies the amount of graphite present in the slate, as well as oils and other organic matter. If the slate contains in excess of 2% graphite, it fails the test and does not pass the European standard.

Carbonate Content

These groups determine the thickness of the slate. The groups also determine the method of sulphur dioxide testing,

Sulphur Dioxide Exposure For Slate With Less Than 20% Carbonate

The slate is exposed to sulphur dioxide at two different concentrations for a duration of 21 days. Depending upon changes during the test, one of 3 codes will be given. The code is then used to apply a thickness adjustment, depending on the carbonate content of the slate.

Balach Blue

Sulphur Dioxide Exposure For Slates With More Than 20% Carbonate

The slate is subjected to surface scraping before and after exposure to sulphur dioxide vapor. After each exposure there is an increase in material removed, this carries on until the depth of softening is reached. A thickness adjustment is then applied to all slates, except for in the case where the softened layer is greater than 0.7mm.

Thermal Cycle Test

The slate is subjected to 20 cycles of immersion in water immediately followed by drying at 100 degrees Celsius, upon completion an inspection occurs for the presence of potentially harmful mineral components:

- T1- for slate with colour changes that do not affect the structure and form runs of discoloration.
- T2- for slates with colour runs that do not cause structural change.
- T3- for slates where holes may be formed from the oxidization of inclusion.

If exfoliation, splitting or other structural changes occur, the roofing slate does not pass the test and is therefore not up to European standard.

Petrographic Examination

Geological appraisal that includes optical microscopy, x-ray diffraction and scanning electron microscopy. This examination determines the type of roofing slate and weather there is any presence of harmful or dangerous structures or minerals.
